

What is a Clean Transportation Standard?

An Introduction by the Clean Transportation Standard Network Action Team

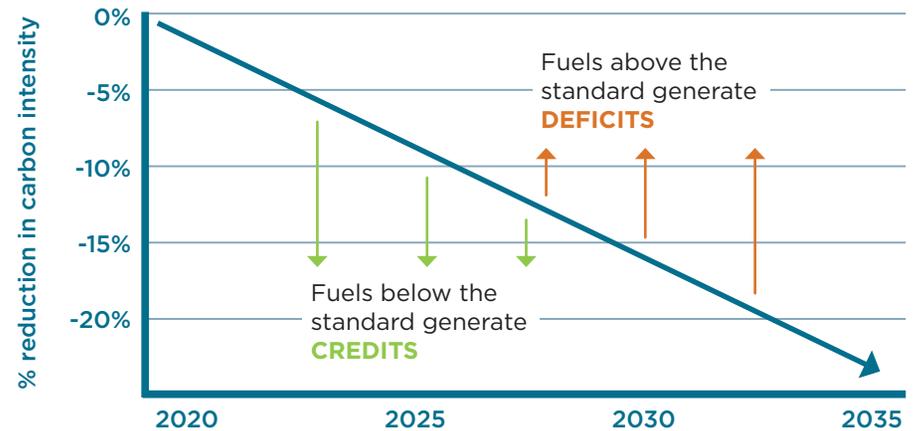

To help Vermont meet the requirements of the Global Warming Solutions Act, a proven approach worthy of consideration is a Clean Transportation Standard: a market-based program that lowers carbon and other emissions in the transportation sector. California enacted a clean transportation standard in 2011, Oregon in 2015, and Washington State followed suit in 2021. The policy assesses all fuels on a carbon intensity (CI) scale that measures their life-cycle emissions. Fuels that pollute more than the CI standard will generate deficits, and fuels cleaner than the standard will generate credits. The credits generated by low CI fuels will make it easier for Vermont businesses to move to electric or clean alternatives. Vermont's dependence on liquid petroleum fuels will not end overnight. A Clean Transportation Standard can immediately reduce this dependence in our existing vehicles while driving innovations and adoption of electric vehicles. Petroleum importers are required to meet these tightening requirements.

Carbon intensity values of different transportation fuels

Source: Oregon Clean Fuels Program, Department of Environmental Quality: Fuel Pathways - Carbon Intensity (CI) Values. The carbon intensity values for the program are expressed in grams of carbon dioxide equivalent per megajoule of energy (gCO₂e/MJ). VT electricity carbon intensity figure is added by EAN and based on 2019 data from ANR of 15 lbs/MMBTU or 52 lbs/MWh. California Low Carbon Fuel Standard average CIs based on LCFS Data Dashboard updated 4/29/22.

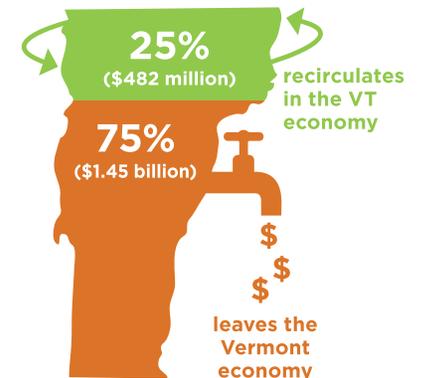

Declining carbon intensity curve

A switch to electric vehicles, heat pumps, and/or advanced biofuel energy often allows consumers to save money year after year with lower-cost, price stable renewable alternatives, while helping to create good, local jobs. The efficient and renewable alternatives keep a higher share of our energy dollars recirculating in Vermont, helping employ our neighbors and improving our state economy.

What does Vermont's transportation system look like today?

Transportation Facts

Petroleum-based fuels accounted for about **95% of the total energy** used by the Vermont transportation sector in 2019, and **40% of VT GHGs**.

In 2020, Vermont had **525,000 gasoline vehicles** and **4,400 EVs** (both AEV and PHEV).

Diesel consumption

- 80 million gallons inclusive of off-road
- 2 million gallons of biodiesel

Electricity consumption

- >1 million Gasoline Gallon Equivalents of electricity

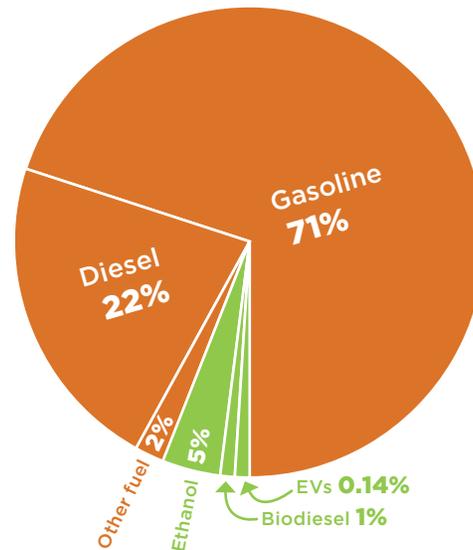

Gasoline consumption:

- 270 million gallons per year
- 30 million gallons of ethanol

Other states, including California and Oregon, already conduct lifecycle emissions analysis related to transportation energy use, building on the GREET model developed by Argonne National Labs.¹ GHG emissions from a broad fuel type can vary depending on unique characteristics. **In particular, different biofuels have very different lifecycle emissions factors (or carbon intensities) based on how each fuel is sourced and produced, so it is important to distinguish between them rather than lump them together.**

Lifecycle analyses of biofuels can and should also account for emissions related to both direct and indirect land use change, as Oregon, California, and Washington do for assessing compliance with their Clean Fuels policies.

What could Vermont look like in 2030 with a Clean Transportation Standard in place?

Clean Transportation Standard policies in other parts of the U.S. have demonstrated that the fuel mix can be decarbonized and diversified quickly by providing policy certainty and meaningful incentives. Vermont can reduce pollution and distribute economic benefits more equitably.

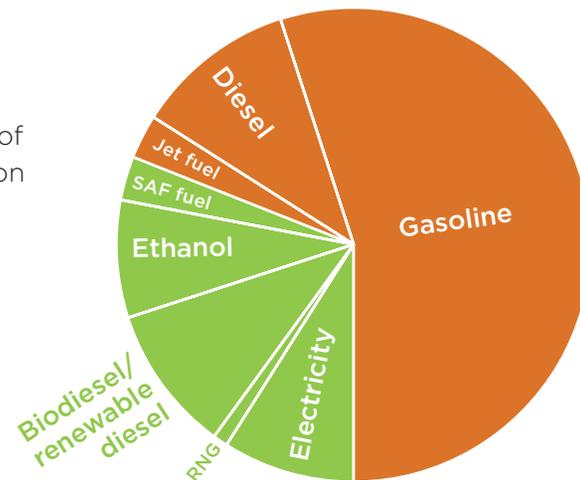

In addition to increasing the number of electric vehicles, a clean transportation standard allows farmers and their commodity suppliers to provide renewable fuels to compete directly with fossil fuels. Such renewable fuels reduce greenhouse gases and substantially reduce air pollution compared to diesel and gasoline, creating real health benefits.¹ Building markets for biofuels can decrease the cost of food by adding demands for both proteins and oils and bolsters innovation in the bioeconomy.²

Existing liquid fuel and gas

infrastructure, equipment, and vehicles can be utilized with biofuels to displace fossil carbon and reduce harmful pollutants in sectors of our economy that will be difficult to reach with electrification; for example freight transportation, heavy-duty construction vehicles, and some farm vehicles. Any strategy that reduces carbon intensity wins in a clean fuel standard. Biofuels provide the additional benefit of transforming wastes and co-products of food production into carbon reducing and cleaner emitting fuels — today. Low-emission fuel options that can be deployed safely and immediately offer tangible results for our planet, our state, our rural economies, and public health.

Energy sources for VT transportation in 2030, with CTS potential
